concentration the flame temperature was lower on the axis than at the periphery and where the concentration evened up so did the temperature. The CO₂ and O₂ concentrations became stabilized beyond the point where flame-type combustion reached the axis of the fuel/air flow. This the time of ignition is commensurate with the combustion time, a conclusion which is supported by analysis of fuel samples taken from the flame. The influence of the ratios of supply of primary and secondary air are discussed. The degree of blackness of the flame was higher than usually reckoned reaching a maximum value of about 0.8 for Yorktown gas coal and up to 0.85-0.9 for lean coal and anthracite with a mean value of 0.65 to 0.75, which is in good agreement with data recently obtained by the International Commission on Flame study. The relationship of a maximum to the degree of blackness does not depend on the total value of the stoichiometric coefficient nor on separation from a powdered fuel flame. The effect of the burning time does not affect the maximum value of the coefficient of the flame. The burning time influences the variation of the variation of the flame temperature and that variation can be related to the variation of the temperature with time.

require correction. The best developed method of making calculations is that of V.V.Pomerantsev, S.L.Shagalova and K.M.Aref'yev (Teploenergetika, no.11, 1958) which gives results that are in good agreement with the data from full-scale furnaces in service. Accordingly, this method was applied to the present tests which were on a much smaller scale than a normal furnace and once again agreement was found to be good. The tests gave somewhat higher degree of blackness for anthracite and lean coal than for gas coal which implies that the basis of the Soviet standard method of calculation is wrong. For gas coals the degree of blackness is actually appreciably below the calculated value whilst for anthracite the calculated values are too low. This is because the main source of radiation is burning particles of coal and not hot gases or volatiles, as assumed in the calculations. There are 9 figures and 2 tables.

TITLE: The Nature of the Precipitates which Separate Out from
Modified 12% Chromium Steel at Temperatures above 550°C
(Podstata precipitátů vylučujících se z modifikovaných
12procentních chromových ocelí v oblasti nad 550°C)

PERIODICAL: Hutnické Listy, 1959, Nr 5, pp 469-472 (Czechoslovakia)

ABSTRACT: (Czechoslovak Metallurgical Research Reports).
The authors studied the precipitates of 12% Cr steels
alloyed with small quantities of W, Mo, V and in some
cases also Co (full analyses of the tested steels are
entered in Table 1, p 469) after various heat treatment
procedures, using chemical, electrolytic and extraction
separation and electron and X-ray diffraction analyses.
It was found that in steels, which in addition to
chromium contain tungsten as the main alloying element,
the inter-metallic phase Fe_2W separates out from the
 δ -ferrite and sorbite after long duration annealing.
This phase occurs in steels with δ -ferrite as well as
in purely martensitic steels and its range of existence

contd 1/2

The Nature of the Precipitation which Separates Carbide from Mottled
12% Chromium Steel at Temperatures above 550°C

extends to the A_{c1} temperatures. In steels which have an increased Mo content and no W the isomorphous inter-metallic phase Fe_2Mo is present, the range of existence of which does not exceed 700°C. In chromium steels which do not have any further alloying additions, a small quantity of the nitride Cr_2N forms in addition to the carbide $(Fe,Cr)_{23}C_6$.

TITLE: The properties of Cr-Mo-V type heat-resisting stainless steel at temperatures up to 600°C

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 17, 1962, 14 - 15,
abstract 17A99 ("Materiál. sb." 1960. Čast 2". Statni výzkumný ústav
materiálu a technol. Praha, 1960, 7 - 24, Czech; summaries in Russian
and English)

TEXT: The results are reported of a study of the effect of heat treatment and the amount and form of δ -ferrite separation on the impact toughness, fatigue strength, internal friction, heat resistance, structure stability and the tendency to temper brittleness of 20Cr12 Mo2V type stainless steel in the 450 - 650°C temperature range. The data obtained entitle to a conclusion that the steel of the said type, used for steam turbine blades for operation at 600°C, must contain not more than 10 - 15% δ -ferrite. Temperature regions of existence of intermetallic phases are established.

TITLE: Properties of chromium creep-resistant steels of the
12% Cr type for castings with further additions

PERIODICAL: Strojírenství, 1961, Vol.11, No.9, p.712

TEXT: On thirty laboratory heats of stainless chromium steels with various inoculations, the mechanical properties, the creep resistance, corrosion resistance and structural stability under conditions of long duration annealing as a function of the chemical composition and the heat treatment were investigated. As a result, three types of cast creep-resistant chromium steels are recommended: type 18 Cr 11 Mo 1 V for larger castings with larger wall thicknesses, type 18 Cr 11 Mo 2 V for medium and small castings and type 20 Cr 11 Co 2 W 2 V for small, highly stressed, castings. The first two are capable of substituting the more expensive austenitic steels.

AUTHOR: Pluhář, J. (Czechoslovakia)

TITLE: Development of corrosion-resistant steels for the chemical and power engineering industry

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov, no. 5, 1962, 52

TEXT: The paper was presented at a symposium on stainless steel.

It contains a review of new Czechoslovak stainless steels with a reduced nickel content. Austenitic refractory steels developed in Czechoslovakia in 1957, intended for operation up to 650 °C: steel Mn17Cr7Ti (CSN 17481), steel Mn17Cr10V (CSN 17482) and steel Mn17Cr7MoV (CSN 17483). At 650 °C the steel Mn17Cr7MoV has a strength under prolonged conditions of loading of $10\ 000 = 8\ \text{kg/mm}^2$ and was the most economical for operation at this temperature; it is used for components of superheaters, boilers and steam piping. Deformed (forged) and

Card 1/3

Development of

S/129/62/000/005/009/011
E073/E335

cast Cr-Ni-Mn steel Poldi AKM (ČSN 17460), which contains up to 0.12% C, 18% Cr, 8% Mn, 45% Ni and 25% N is being used in Czechoslovakia. An additive material for welding steel sheet has been developed which permits using this steel to weld structures in the cold state. This additive consists of a mixture of the following components: 1) aluminum, 2) magnesium, 3) calcium, 4) titanium, 5) zirconium, 6) vanadium, 7) niobium, 8) molybdenum, 9) tungsten, 10) tantalum.

The new additive makes it possible to weld the steel AKM at temperatures down to -196°C. The additive is also used for the manufacture of the dispersion-hardened steel 17-7-Al-Ti and of the steel Cr20Mn10. The additive is made of the following materials: 1) aluminum, 2) magnesium, 3) calcium, 4) titanium, 5) zirconium, 6) vanadium, 7) niobium, 8) molybdenum, 9) tungsten, 10) tantalum.

The new additive is being developed for welding austenitic steels and for the manufacture of the corresponding austenitic steel. Results are also available which are intended for castings. These steels are welded with electrodes

made of the steels Cr18Ni5Mn8N and Cr18Ni8Mn6. Of the two-phase austenitic-ferritic steels, the manufacture of the dispersion-hardened steel 17-7-Al-Ti and of the steel Cr20Mn10 has been achieved in Czechoslovakia. It is assumed that in 1965 55-40%

AUTHOR: Pluhar, Jaroslav

TITLE: Stainless chrome steel with Mo and V admixture for use at temperatures up to 600°C

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 12, 1962, 73,
abstract 12I434 ("Wiss. Z. Techn. Univ. Dresden", 1962, v. 11,
no. 2, 375 - 384; German)

TEXT: A description is given of the structure, mechanical properties at room and elevated temperatures, and corrosion resistance of four modified 12% Cr-steel grades, containing 0.18 - 0.23% C and 0.89 - 1.42% Mn. Three grades contained Mo (2.2 - 2.7%) and V (0.24 - P 32% (?)); the fourth grade contained 4.59% W and 6.25% Co. The Mo-V steels were oil-quenched from 1050°C and tempered at 660 and 740°C (σ_s was 94 - 100 and 79 - 85 kg/mm² respectively, σ_b was 78 - 80 and 55 - 61 kg/mm²). W-Co steel was tempered for 5 hours at 680°C (σ_b was 110 - 112 kg/mm², σ_s was 88 - 91 kg/mm²). The results of endurance tests of Mo-V steel within a temperature range from 550 to 650°C are given in the form of a Larson-Miller diagram, which shows that one part of the heats possessed reduced Card 1/3

S/137/62/000/012/044/085

Stainless chrome steel with Mo and V admixture for... A006/A101

endurance strength. An analysis of the microstructure has shown that heats of reduced strength contained besides streaky ferrites, sorbite, infiltrated with ferrite islets. In heats of higher endurance strength, the sorbite base was separated from the ferrite streaks. As modified Cr-steels are mainly intended for turbine blades, the authors studied fatigue strength under alternating tension-compression and rotating bending conditions at 20 and 600°C. It was found that at 600°C the slope of fatigue curves increased with a greater constant stress component σ_T ; at $\sigma_T = 30 \text{ kg/mm}^2$, the Weller curve breaks off after less than 10^8 cycles. The corrosion resistance of modified Cr-steels in overheated steam at temperatures up to 700°C can be compared to the resistance of conventional 13%Cr steels and is not different from that of low-alloy heat-resistant Cr-Mo and Cr-Mo-V steels at temperatures up to 560°C. Modified Cr-steels are prone to brittleness after extended holding at high temperatures. The degree of embrittlement is the higher, the greater the δ -ferrite amount in the steel. Therefore the steel composition should be selected in such a manner that the amount of δ -ferrite should not exceed 15%. Analyses of the carbide deposit after holding at different temperatures show that the deposit base is $M_{23}C_6$ carbide. M_2C carbide was detected in considerably lesser amounts. At temperatures over 600°C Loves' phases

~~CHROMIUM STEEL~~TOPIC TAGS: chromium, stainless steel, ~~chromium~~ heat resistant steel, molybdenum containing steel, vanadium ~~containing~~ steel, ~~SOLID~~ mechanical property/ARM steel

ABSTRACT: CSN 42 2916 heat-resistant stainless steel (0.16—0.22% carbon, 10.2—11.8% chromium, 0.90—1.20% molybdenum, and 0.20—0.35% vanadium), intended for cast parts used in the power and chemical industries, has been developed. In heat-treated condition (annealed at 1040—1070°C, air cooled and tempered at 720—750) the steel has a tensile strength of 65—85 kp/mm² and the following minimum values of other properties: yield strength 45 kp/mm², elongation 15%, reduction of area 30%, and notch toughness 4 mkp/cm². The 100,000-hr rupture strength at 550 and 600°C was 12.4 and 7.4 kp/mm², and the creep strength (1% total deformation in 100,000 hr) was 8.3 and 5.0 kp/mm², respectively. TITLE: Structural stability of austenitic manganese steels, 6

SOURCE: Kovove materialy, no. 6, 1965, 526-548

TOPIC TAGS: metal heat treatment, austenitic steel, manganese steel, carbide phase

ABSTRACT: Based on results of tests the authors offer the following conclusions. The austenitic structure in modified Mn steels of the type investigated is less stable than in steels of the classical type. The austenite in manganese steels containing more than 8% Mn remains stable up to -100C. It also remains stable after plastic deformation and subsequent freezing over the entire temperature range including deformation up to 30C and freezing down to -50C. Aside from phases forming the decomposition product of austenite during isothermal annealing of classical manganese, ferritic and bainitic reactions were found to take place. The regions and boundaries of all phases were established. Classical and modified steels show two hardness peaks as a function of temperature and isothermal annealing. The second

Card 1/2

I 31947-66

ACC NR: AP6018258

peak has not been reported elsewhere. The region of the first hardness peak is characterized by the precipitation of the carbide phase and the formation of pearlite or bainite. The region of high temperature maximum is produced by martensite formed in specimens cooled down from the annealing temperature. The process taking place during continuous slow heating can be equated with changes under isothermal conditions. Thermal hysteresis increases with the rate of heating and with a lower reaction temperature. The amount of transformed austenite is smaller with continuous heating. Changes appearing in the solid solution during the initial stages of continuous heating can be related to the formation of atmospheres of interstitial atoms on packing defects. This process precedes the precipitation of carbides. The article was reviewed by Frantisek Poboril, Research Institute of Ferrous Metallurgy, Prague. Orig. art. has: 21 figures and 4 tables. [GC]

TITLE: Method of Creating Surface Layers on Articles Made of Austenitic Steel, and Alloys

SOURCE: Hutnické listy, no. 2, 1964, 147

TOPIC TAGS: Surface Hardening of Steel, austenitic steel, steel alloy

ABSTRACT: The problem of a simple and technically and economically feasible method of creating surfaces of special properties on objects made of austenitic steel and alloys, especially manganese alloys, which would have a composition such that the removal of certain elements determining the austenitic structure would bring about a conversion of the austenite to another phase, has been solved by a discovery. According to the discovery, in order to create a hard wear-resistant surface of steel or alloy, an element, or elements accelerating the diffusion of carbon or other austenite-formed elements can be used, after which, the articles are kept for from one to 20 hours at temperatures from 800 to

Card 1/2

ACCESSION NR: AP4012492

1,200°C in a medium which combines one or more austenite-formed elements. The rapid diffusion of carbon as a result of the higher temperature from the surface of the part, which combines with the surrounding medium, which includes the compounds that are combined with it, such as ferr oxygen, creates a sufficiently deep surface grade with high surface hardness on the surface of the part.

Formation of hydroxamic acids from peptides. III
Specificity of glutathionease. Karel Slavík, Blanka Hudlická,
and Věra Matoušková (Fak. farmacie Univerzity Karlovy v Praze).

J. Physiol., 197, 43, 1078-81 (1954); cf. C.A. 46, 112445.
Transpeptidation (by way of hydroxamic acid formation) and hydrolysis of simple γ -glutamyl peptides by means of glutathionease were followed by paper chromatography. The sequence for transpeptidation was glutamine > γ -glutamylglycine, γ -glutamylglycinamide > γ -glutamyltyrosine; sequence for hydrolysis was γ -glutamylglycine > γ -glutamyl-glycine amide > glutamine > γ -glutamyltyrosine. Hydrolysis and transpeptidation occur with γ -amino acids, having a COOH group in the γ position; their rates depend on the substituents bound to the γ -amino group. Glutathionease is not stereo-specific, but the rates of hydrolysis and transpeptidation of D-glutamic derivs. are lower than those of the L antipodes. M. Hudlický

TITLE: Study of certain electrophysical properties of low-molecular-weight charge-transfer complexes introduced into polymer films

SOURCE: Elektrokhimiya, v. 2, no. 6, 1966, 732-734

TOPIC TAGS: organic semiconductor, charge transfer complex, photoconductive material

ABSTRACT: The electrical properties of low-molecular-weight charge-transfer complexes (CTC) are usually studied with donor-acceptor multilayer specimens, as with powder or film specimens prepared by depositing CTC from solutions. However, the reproducibility of electrical measurements using low-molecular-weight CTC films deposited from solution is poor owing to nonhomogeneity. Therefore, a study has been made of the feasibility of preparing new polymeric photosensitive semiconductors, whose properties can be predetermined by introducing CTC in polymer film "matrices." The acceptor, p-chloranil (PCA), and the donor, p-phenylenediamine (PPD), were introduced into polyacrylonitrile

Plame, Z. Solution of Neumann's boundary problem in potential theory by singular integral equations. Latvijas PSR Zinātņu Akad. Vēstis 1950, no. 8(37), 119-126 (1950). (Latvian, Russian summary)

The interior Neumann problem for a plane domain bounded by a curve L having a Hölder continuously turning tangent (but in general no radius of curvature) is solved by using singular integral equations. The solution is represented as a potential of a double layer. [For a similar treatment of the Dirichlet problem see G. Beryand, Bull. Sci. Math. (2) 47, 282-288, 298-307 (1923); N. Muskhelishvili, Soobshch. Gruzin. Filial. Akad. Nauk SSSR 1, 99-106, 169-170 (1940); these Rev. 1, 314.]

Takbar, I. M. and Plume, Z. Ya. Some boundary problems
of the theory of transverse magnetization.

The authors treat the problem of finding the magnetic induction of an infinite, circularly cylindrical, conducting wire of unit radius by the application of an external magnetic field. The wire has constant conductivity and permeability which are different from the axis and other directions. The ratio of the resistivity and permeability between 1 and the axis is

value which is a parameter of the problem. It is shown that when the ratio of the resistivity and permeability is small ($\Delta \gamma \rightarrow 0$) the magnetic field in the wire is zero at the center, and the magnetic field outside the wire is finite.

PLUMYE, Z. Ya.

The Dirichlet Problem of the Theory of Differential Equations of Elliptic Type in the Case of Open Contour Izv. AN Latv. SSR, No 2, 1954, pp 129-136

The author introduces an elliptic type differential equation and solves the Dirichlet problem when certain boundary conditions are imposed. The holomorphic function entering into the general representation of the solutions is expressed with a Cauchy integral, and the problem is reduced to a singular integral equation. TITLE: Intensifying Processes of Plasticisation and Mixing on Roll Mills (Intensifikatsiya protsessov plastikatsii i smesheniya na val'tsakh)

PERIODICAL: Kauchuk i Rezina, 1958, Nr 6, pp 34 - 35 (USSR)

ABSTRACT: The aim of the investigation was to intensify the plasticisation of natural rubber and colouring of mixtures whilst working on rollers (temperature of the roller = 50° - 60°C) by using non-toxic plasticisers. The first stage of the investigation consisted in testing, under laboratory conditions, substances recommended by NIIR, NIIShP and the Lomonosov NITKhT. (1) Anti-oxidants: dimethylphenylparacresol (DMFPK), mercapto-benzimidazol (NB), tri-tert.-butylphenol (P-23), di-tert.-butylhydroquinone (P-20). (2) Vulcanisation accelerators: tetramethylthiuramdisulphide (thiuram), peroxide (isopropylbenzene hydroperoxide), chlorinated paraffin, ferric stearate, bis-(para-tert.-butylphenol) disulphide and renatsit H. The effect of these various substances was tested; however, negative results were obtained.

The investigation of the thermohydrolysis process of plant materials. M. N. Plungianskaya and M. G. Gan. *Trudy Nauch.-Issledovatel. Lab. i Op. Stantsii Barkabata* 1937, 33-47; *Khim. Referat. Zhur.* 1, No. 7, 851 (1938). The dependence of the physicochemical properties of Barkabite on the autoclave conditions (with a pressure of 14, 12, 10, 8 and 6 atm.; the max. pressure kept for 1 hr.) and on the amt. and manner of the water added (with a 3 and 7 atm. pressure the added water for each variant was 30, 100, 160% of the abs. dry wt. of the raw material) was investigated. Analyses of the vapor phases and of the resulting products were performed for each case. All substances contained in the steam-gas mixt. obtained during the thermohydrolysis, in the dry powder obtained after the autoclave reaction, and in the steam-gas mixt. obtained after the pressure reaction were detd. Conclusions: CO_2 is the main gas component of both phases; no traces of CO , CH_4 or of any unsatd. hydrocarbons were found in the gas phase; the main component of the condensate was AcOH whose content was increased with an increase of the temp. and pressure; the amt. of lignin in the powder is increased, and the cellulose in the autoclave reaction process is only slightly decompr. W. H. Henm
